Devin Renn (DevinRenn), Roberto Sierra (ruken1)*

Project Description

In our group project we developed Quic, a flashcard study website. Our goal was to make studying easier and more fun for students so they wouldn't think of it as studying. Our application is built around a folder-set hierarchy. Users create folders, and within those folders they can create multiple sets. You can think of a folder being like a class and a set being like a topic in that class. When you click on a set it takes you to the flashcard page where you can create, edit, and study your flashcards. The flashcards you make in one set are unique to that set. This structure makes it easy to navigate and manage large amounts of data. When you are working with the flashcards you are given 2 options, edit mode and study mode. Edit mode is where you create, edit, and delete flashcards. Study mode is where you study by viewing a carousel of the flashcards. You can click on the visible flashcard to reveal the opposite side and you can also navigate the carousel in both directions, forward and backward. We also included a profile page which tracks user information like the number of folders you have, your username, and other important information.

Contributions

Zachary Bolon's Contributions

I worked on the home and set page in the project. My job was to create the front end for

each page and then implement the backend logic for it. This included creating the folders and sets on the home page and implementing the backend for it. On the set page I created the flashcards and the carousel for the flashcards, again implementing the backend for it. I would do the front end first and then the back end so I could have a visual of what I was doing.

Max Caron's Contributions

I primarily worked on the profile page and edit buttons. The profile page displays the user's name, username, and total number of folders, sets, and flashcards using database queries. The profile page also displays all of the users folders and sets and allows the user to click on individual sets, redirecting the user to that respective set page. The edit buttons allow users to change their display name, username, and the content of their folders, sets, and flashcards. I also contributed towards the navigation bar logic.

Leydi Maya's Contributions

I set up the foundational structure of the register page and worked on the visual design of the application. I created a color palette to match the comic book theme of our web application, and coordinated the layout to maintain consistency across pages. I helped style core elements like the navbar, home page cards, and buttons to reinforce the theme. I also coordinated with the team to ensure the theme, color, and background decisions were agreed-upon aesthetically for user experience

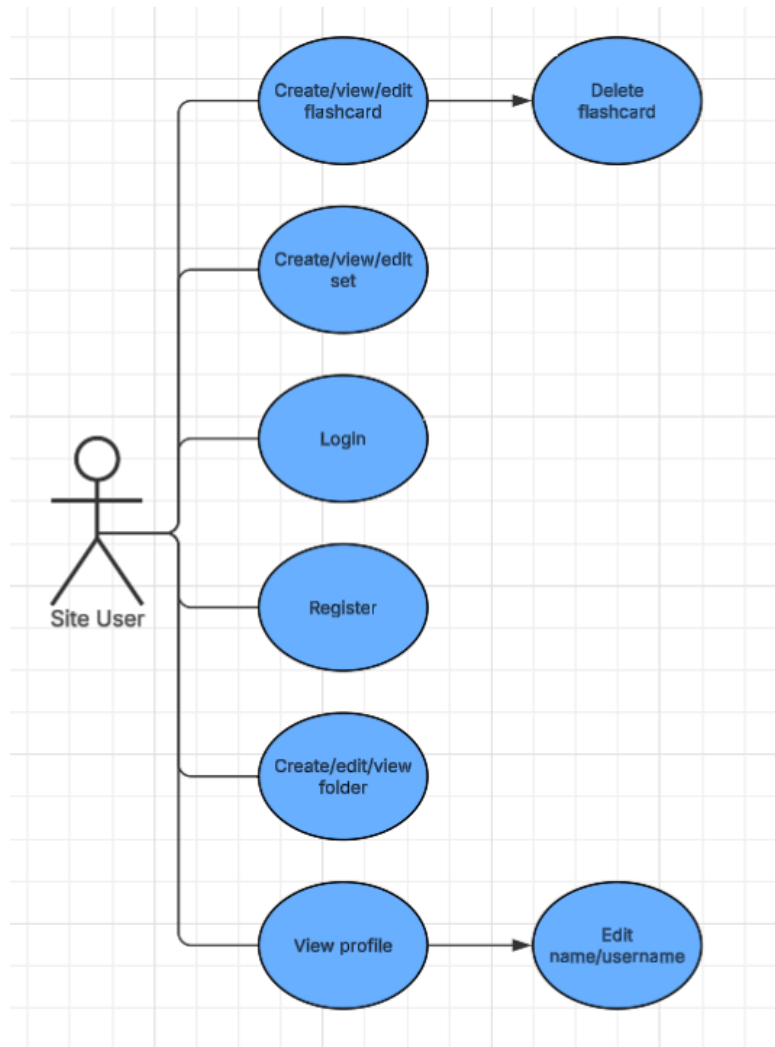

Devin Renn's Contributions

I primarily worked on routing, user authentication, adding test cases, and deploying the project. I set up get/post requests for the login and register pages. I added user authentication such that the user cannot access the home page, profile page, or logout page if they are not logged in. I also created all the test cases and set up the deployment of the project on render.

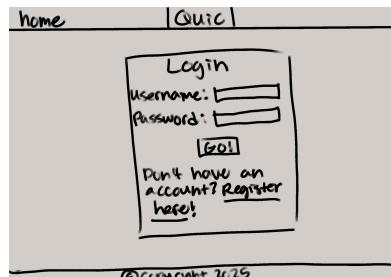

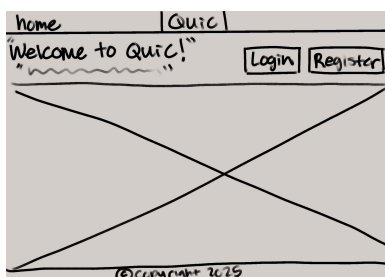

Roberto Sierra's Contributions

I have contributed on the home page, login page, logout page, and register page. I styled, did the logic, worked on the JavaScript within the pages and in the index.js files to give a good impression and experience towards the user. I also connected back or forth between the database and the front end, verifying correct usernames and passwords. I also helped Max on the header and the footer with Handlebars, for example: when the user is logged out, the options change to "login" and "register" instead of "profile", "logout", using conditional logic.

Test Results

Each of the seven test scenarios for logging in, registering, and adding a flashcard produced results that were in-line with the expected test results. More details can be found in the User Acceptance Testing Plan on the git repository [here](#).

In addition to these tests we ran tests on a user who had no idea what the website was. As expected, the user went straight to the register button, made an account, logged into the account, and created a new folder. However, once the user made a folder, they did not click on the “New Set” button like expected and instead tried clicking on the home button and then the profile button. Since you’re not able to create a new set from the profile page, the user did some confused clicking around until eventually they found

the “New Set” button on the home page. From that point, the user was easily able to intuit the website’s functionality and navigated it without issue. The deviation from expected actions with the “New Set” was caused by the user not noticing or expecting the button. In the future this could be improved by either making the “New Set” button larger and brighter to make it stand out more or by changing our current hierarchical structure for storing flashcards in which flashcards are stored in sets which must be stored in folders. It might be more intuitive for the user (especially new users) if they were able to create a set without requiring the set to be in a folder.
